

Observation of associated $W+J/\psi$ production

Peter Onyisi

DPF, 15 August 2013

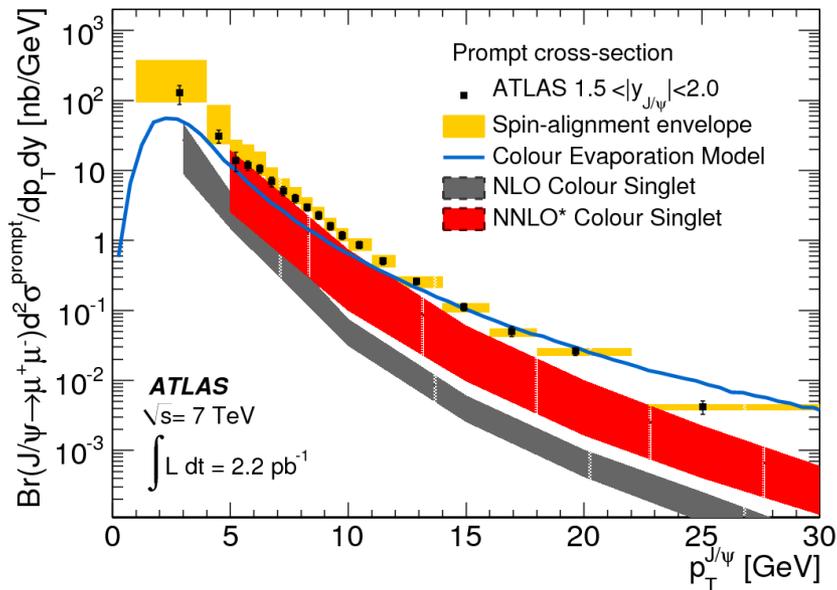

Introduction

- Simultaneous production of charmonium and a weak boson has not been seen at a hadron collider before
- Potentially a good test of production models
- Also sensitive to multiple parton interactions in a single pp collision
- ATLAS has made the first measurement of this process in 4.6 fb^{-1} of 7 TeV pp collisions

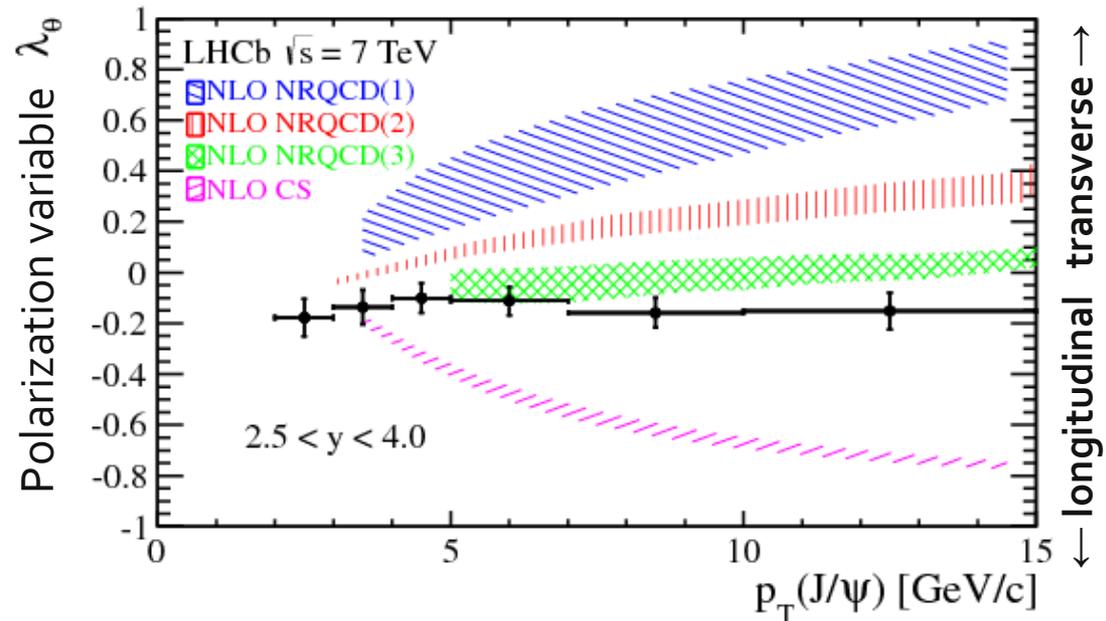

Quarkonium Production

- Quarkonium production in hadron collisions still poorly understood
- Various models fail to predict p_T spectrum, polarization, or both

Nucl. Phys. B 850 (2011) 387-444

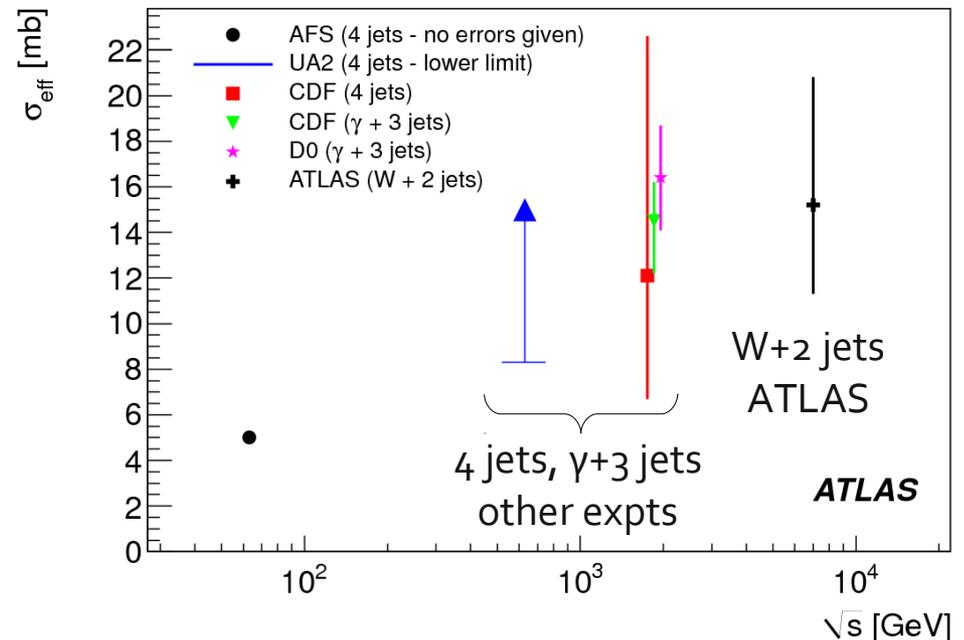

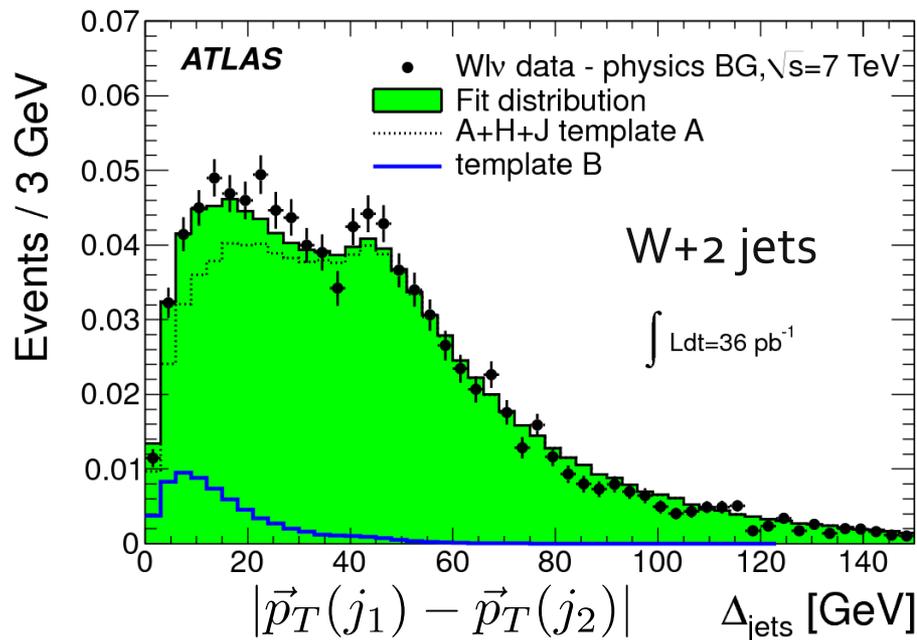

arXiv:1307.6379

Double Parton Scattering (DPS)

- Background for some rare processes
- Probes the structure of the proton (transverse and momentum correlations of partons)
- Strong evidence, but still want to measure and probe universality

New J. Phys. 15 (2013) 033038

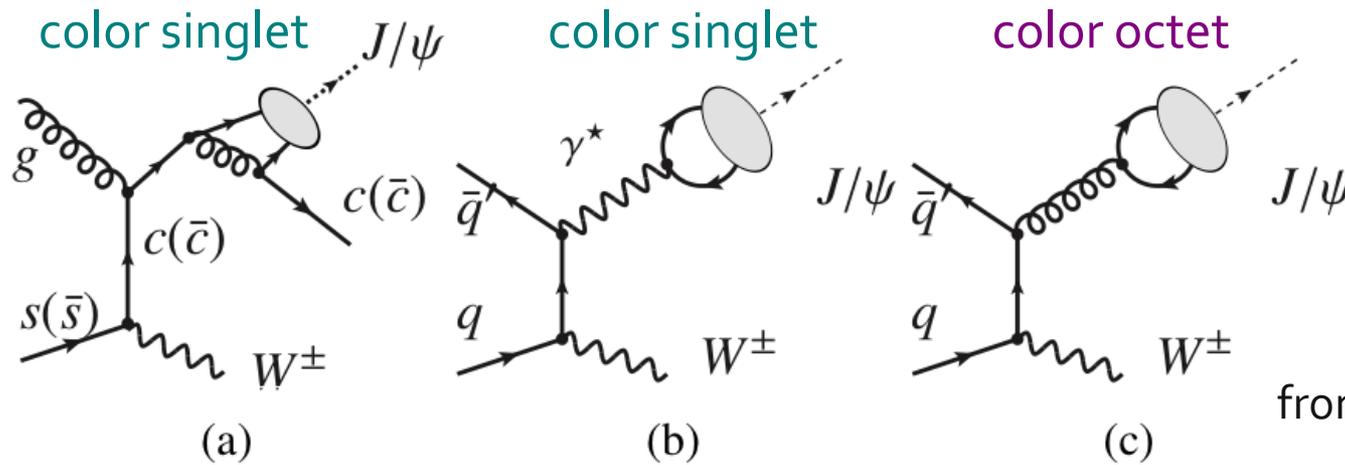

Vector boson + J/ψ

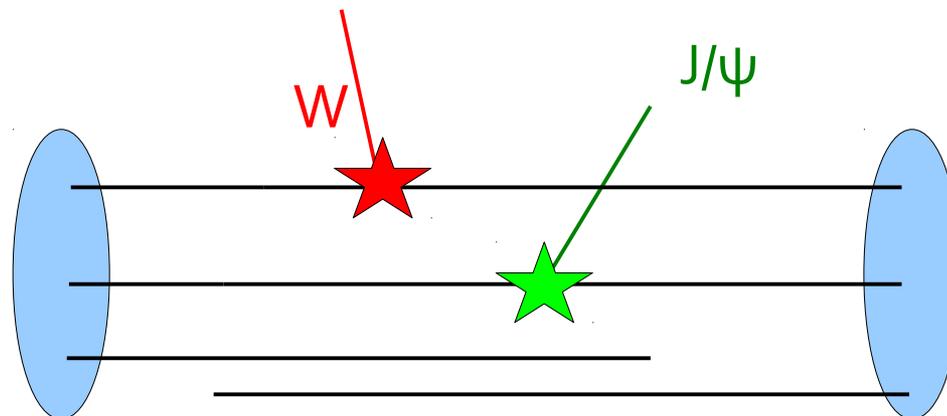

- Interesting probe of both J/ψ production and double parton scattering
 - quark-initiated process selects very different production diagrams than inclusive J/ψ (which is mostly gg)
 - expected single parton scattering production rate small enough that DPS can compete
- Analogous process vector boson+ $Y(1S)$ searched for by CDF (PRL 90 (2003) 221803), limits set
- This talk: ATLAS observation of $W+J/\psi$ (ATLAS-CONF-2013-042)

Production Mechanisms

Single parton scattering (SPS)

Double parton scattering (DPS)

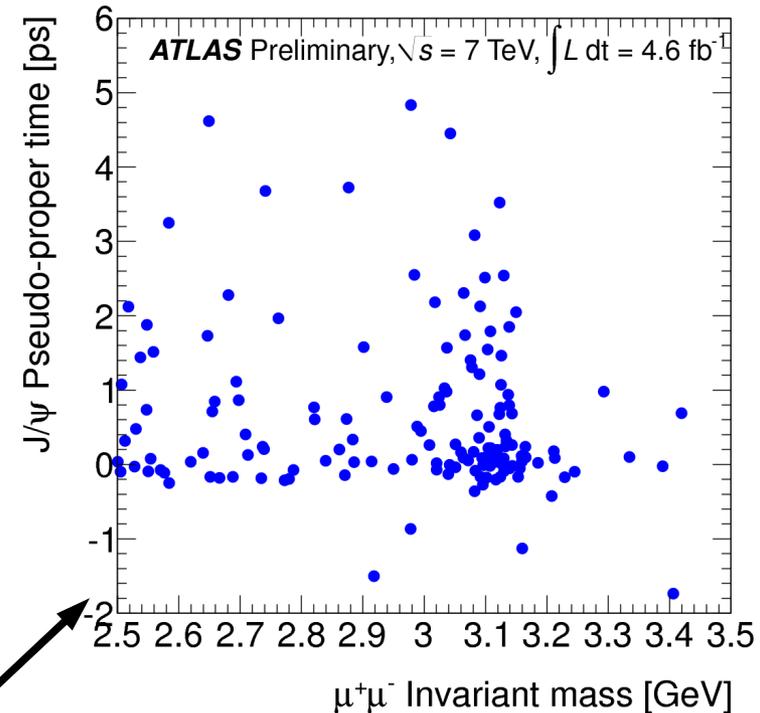

Event Selection

Use the $3\mu + \text{MET}$ channel ($J/\psi \rightarrow \mu\mu$, $W \rightarrow \mu\nu$);
 $W \rightarrow e\nu$ has more background, less efficient

pseudo-proper time

$$\tau \equiv \frac{\vec{L} \cdot \vec{p}_T^{J/\psi}}{p_T^{J/\psi}} \cdot \frac{m_{\mu^+\mu^-}}{p_T^{J/\psi}}$$

Trigger:

- single muon
- $p_T > 18 \text{ GeV}$, $|\eta| < 2.4$

All muons:

- $|\eta| < 2.5$
- $p_T > 3.5 \text{ (} 2.5 \text{) GeV}$
for $|\eta| < 1.3 \text{ (} > 1.3 \text{)}$

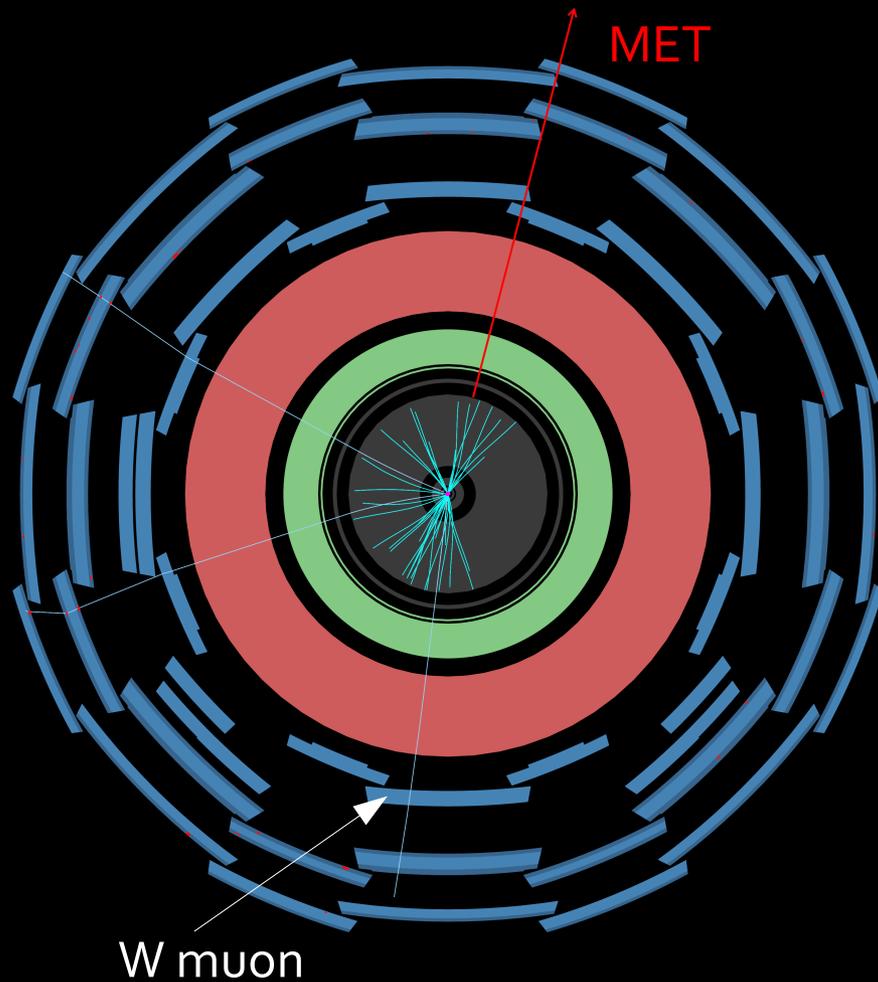

Find J/ψ candidate:

- Two opposite sign μ
- One μ has $p_T > 4 \text{ GeV}$
- $2.5 < m(\mu\mu) < 3.5 \text{ GeV}$
- $|\gamma(\mu\mu)| < 2.1$
- $8.5 < p_T(\mu\mu) < 30 \text{ GeV}$

Find W candidate:

- Use remaining muon
- $p_T > 25 \text{ GeV}$, $|\eta| < 2.4$, fired trigger
- Impact parameter, isolation cuts
- $\text{MET} > 20 \text{ GeV}$
- $M_T(W) > 40 \text{ GeV}$
- Remove events with $|m(\mu\mu) - m_Z| < 10 \text{ GeV}$

J/ ψ

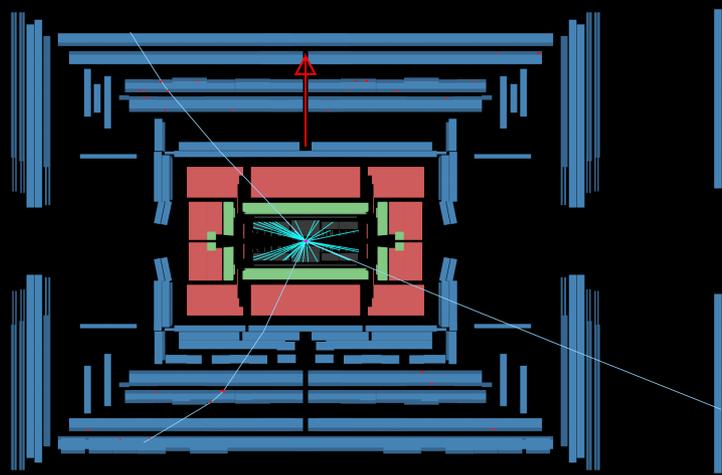

W muon

J/ ψ

W muon

Efficiency Map

- Better low- p_T muon efficiency at high η motivates barrel/endcap separation in fits

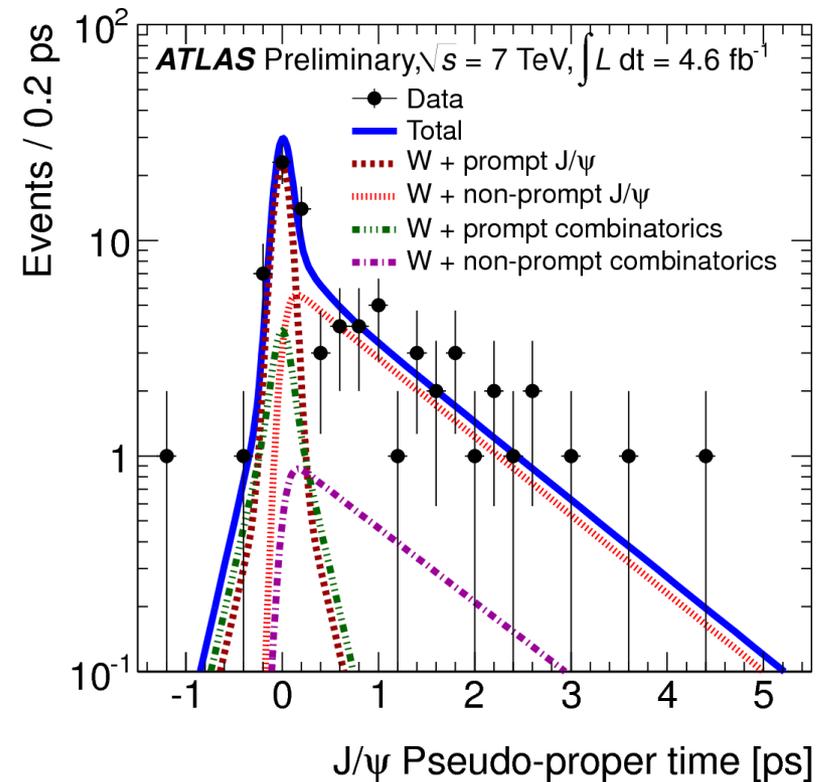

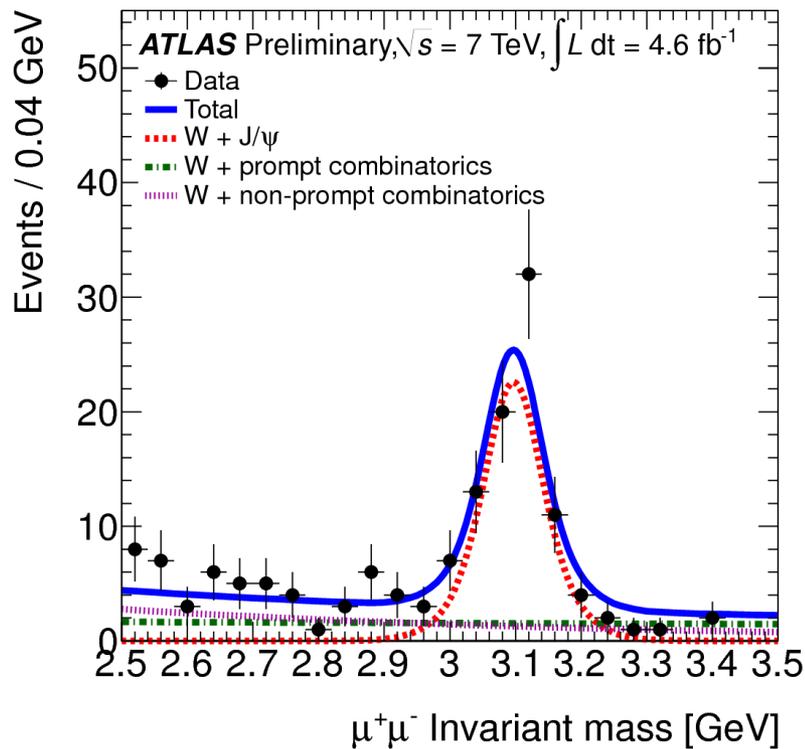

Interpretation

- Do we have prompt J/ψ production in selected 3 μ events?
- Are the prompt J/ψ events compatible with having a W candidate?
 - sPlot technique used to project transverse mass of additional muon + MET
- What do the differential distributions look like?
 - $\Delta\phi(J/\psi, W)$ expected to be a good diagnostic for DPS vs single parton scattering process
 - p_T spectrum also interesting

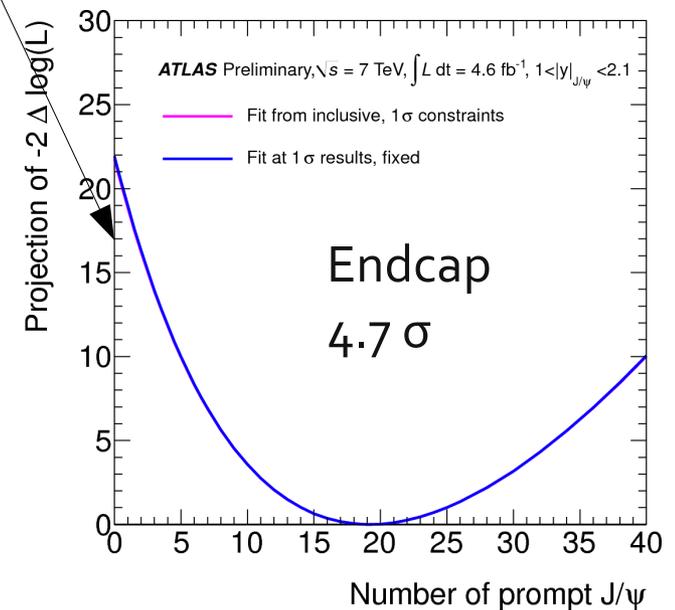

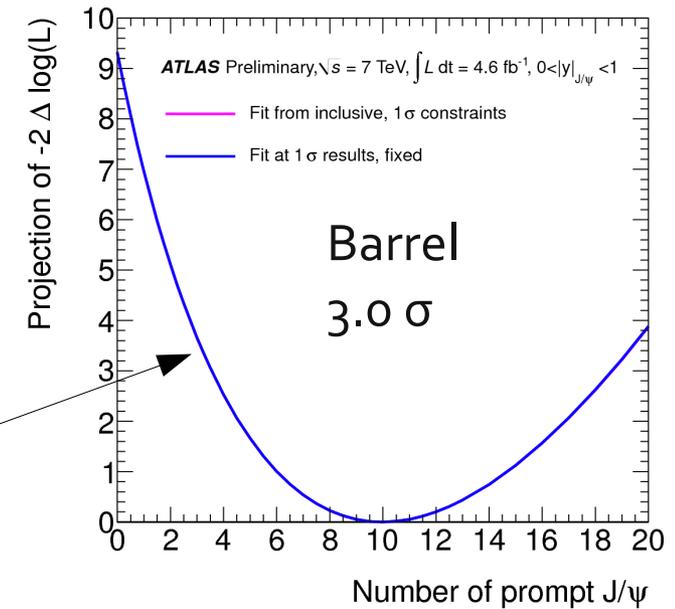

Fits

- Components for J/ψ fit: prompt J/ψ, non-prompt J/ψ, prompt combinatorics, non-prompt combinatorics
- 2D fit in μμ invariant mass and candidate pseudo-proper time
$$\tau \equiv \frac{\vec{L} \cdot \vec{p}_T^{J/\psi}}{p_T^{J/\psi}} \cdot \frac{m_{\mu^+\mu^-}}{p_T^{J/\psi}}$$

Yields

- Significant prompt J/ψ yields for both barrel and endcap candidates
 - Expect larger yield in endcap due to better acceptance in $p_T(J/\psi)$
- Combined significance 5.3σ

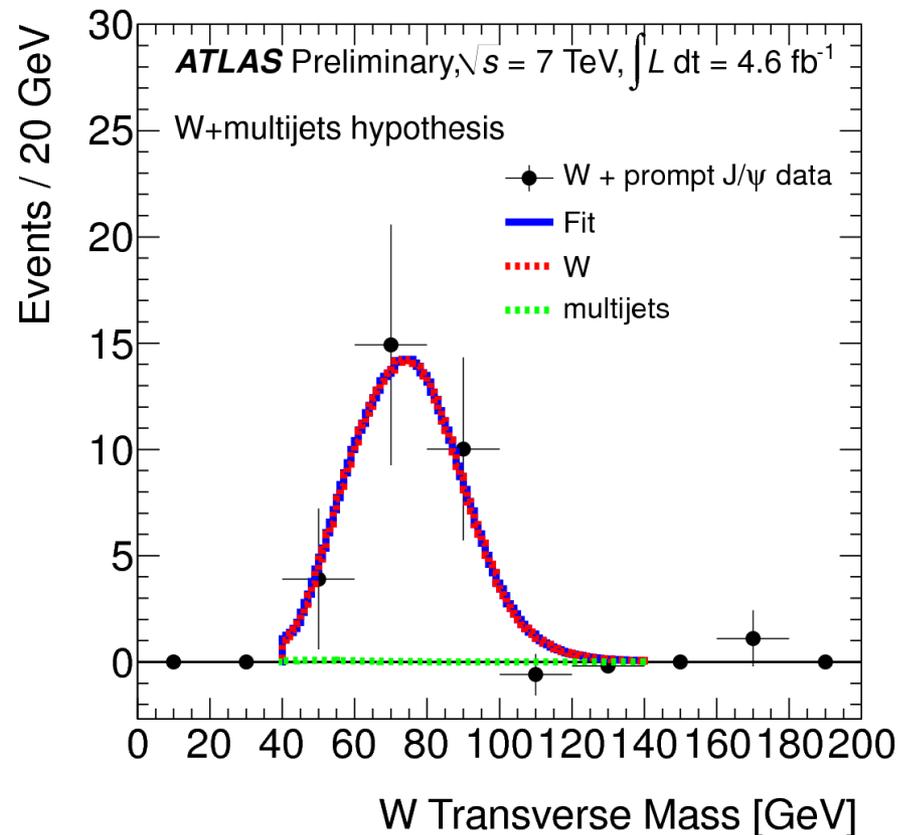

Likelihood contours

Yields from two-dimensional fit

Process	Barrel	Endcap	Total
Prompt J/ψ	$10.0^{+4.7}_{-4.0}$	$19.2^{+5.8}_{-5.1}$	$29.2^{+7.5}_{-6.5}$
Non-prompt J/ψ	$27.9^{+6.5}_{-5.8}$	$13.9^{+5.3}_{-4.5}$	$41.8^{+8.4}_{-7.3}$
Prompt background	$20.4^{+5.9}_{-5.1}$	$18.8^{+6.3}_{-5.3}$	$39.2^{+8.6}_{-7.3}$
Non-prompt background	$19.8^{+5.8}_{-4.9}$	$19.2^{+6.1}_{-5.1}$	$39.0^{+8.4}_{-7.1}$
p -value	1.5×10^{-3}	1.4×10^{-6}	4.4×10^{-8}
Significance	3.0	4.7	5.3

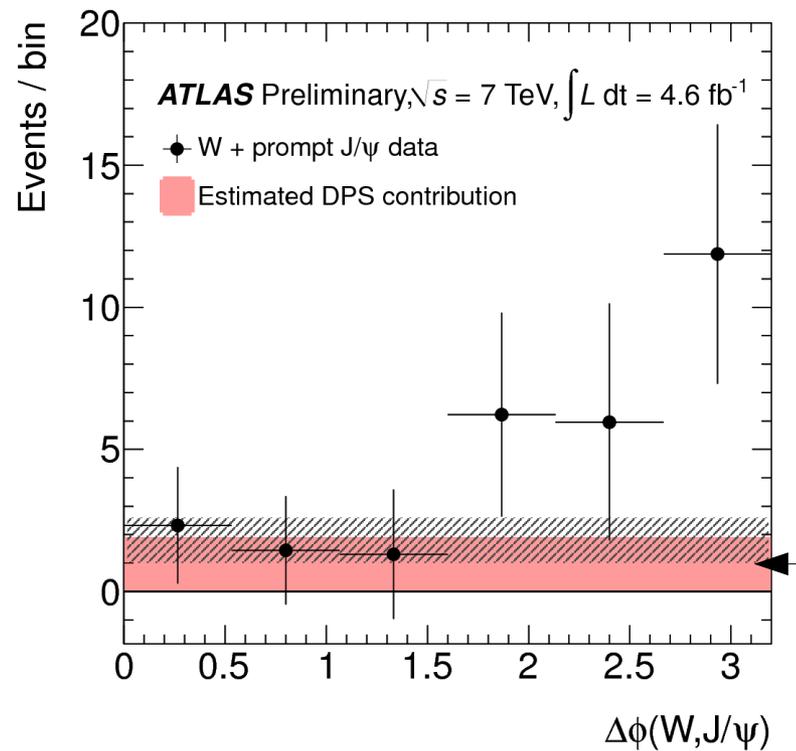

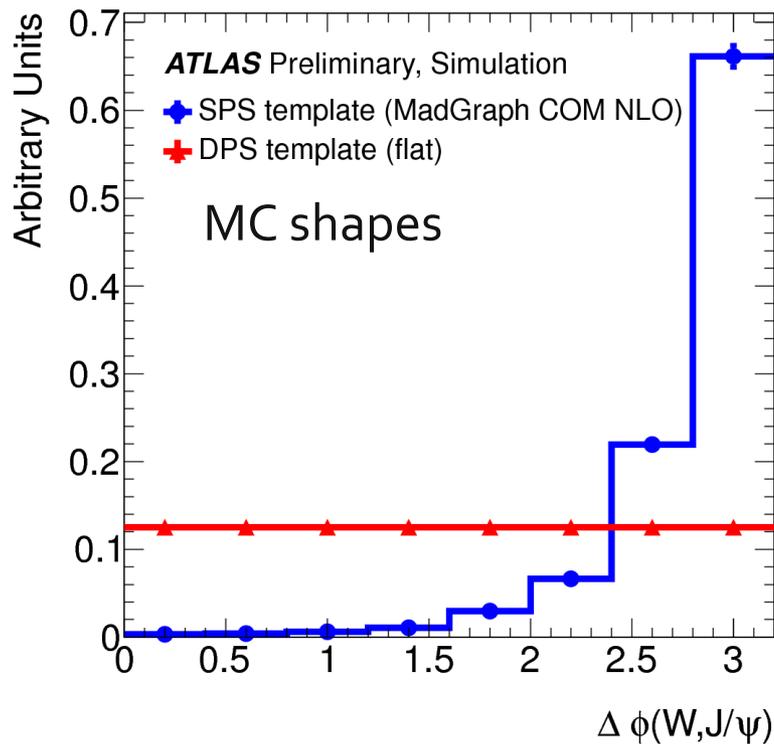

Are these $W + J/\psi$ events?

- M_T distributions very consistent with W
 - multijet contribution $< 31\%$ at 95% credibility level
 - assume 100% $W + J/\psi$ signal

Azimuthal angle

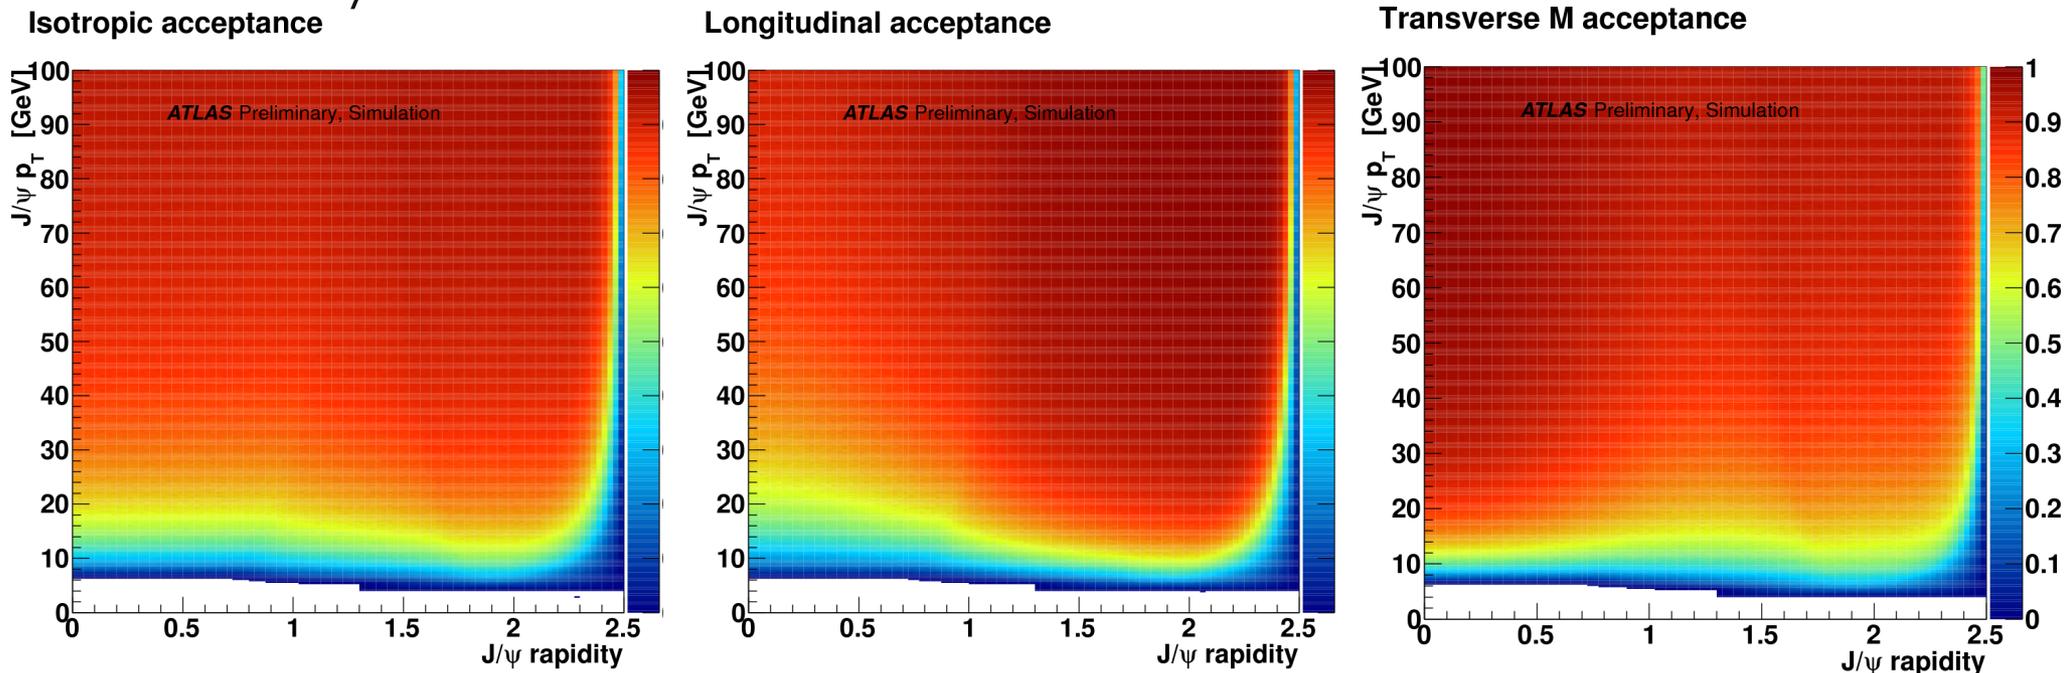

- Diagnostic for SPS (peak at π) vs DPS (flat)
- Low statistics make interpretation difficult but distribution is suggestive of DPS
 - MC SPS shape very model dependent

Prediction of total factorization ansatz

Acceptance/Efficiency Unfolding

- Correct for μ efficiency for J/ψ daughters to get “fiducial cross section”
 - i.e. not corrected for μ outside our kinematic cuts
- Then correct for μ falling outside kinematic cuts to get “inclusive cross section”
 - requires assumption on J/ψ decay angular distribution; envelope gives systematic

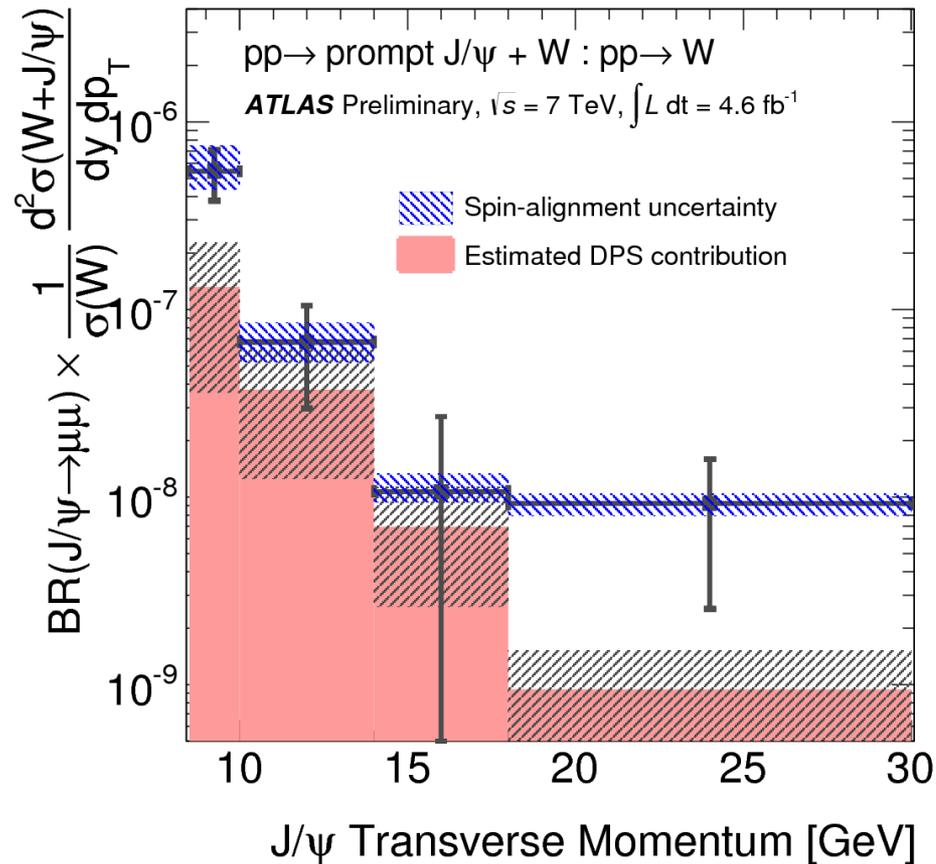

Systematics

- Largest systematic in inclusive measurement from J/ψ decay angular distribution (“spin-alignment”)
- Largest systematics for fiducial measurement from muon efficiency and possible W efficiency non-cancellation
 - None of these affect significance of observation, only central value of measurement

Source	Barrel	Endcap
J/ψ muon efficiency	$\approx 5\%$	$\approx 5\%$
W^\pm boson kinematics	2%	5%
Fit procedure	+3% -2%	+2% -1%
Choice of fit nuisance parameters	1%	1%
Choice of fit functional forms	4%	4%
Muon momentum scale	negligible	
J/ψ spin-alignment	+36% -25%	+27% -13%
Statistical	+47% -40%	+30% -27%

p_T -differential measurement

- Plotted: ratio of normalized differential σ to $\sigma(W)$
- Excess over DPS prediction concentrated in lowest momentum bin $[8.5, 10]$ GeV

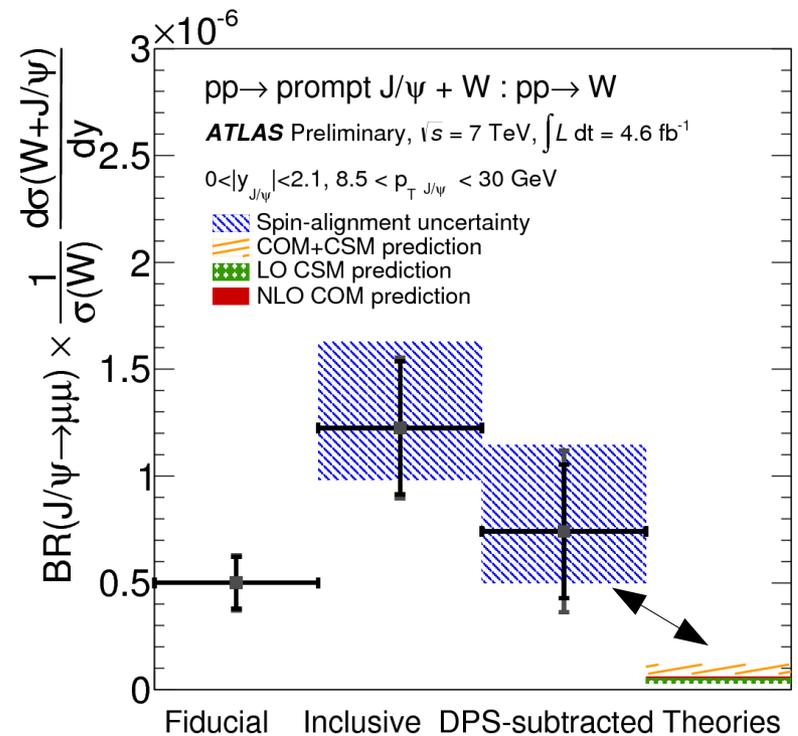

Results (1)

- Numbers are ratio to inclusive $\sigma(W)$
 - in all cases, $p_T(J/\psi) > 8.5 \text{ GeV}$, $|y(J/\psi)| < 2.1$
- **Fiducial** ratio (does not correct for muon acceptance):
 $(50 \pm 12(\text{stat}) \pm 4(\text{syst})) \times 10^{-8}$
- **Inclusive** ratio (corrects for muon acceptance, not for DPS contribution):
 $(123 \pm 31(\text{stat}) \pm 10(\text{syst})_{-24}^{+40}(\text{pol})) \times 10^{-8}$
- **DPS-subtracted** ratio (subtracts expected DPS rate from inclusive):
 $(74 \pm 31(\text{stat}) \pm 21(\text{syst})_{-24}^{+40}(\text{pol})) \times 10^{-8}$

Results (2)

- Theory comparisons of single parton scattering rate:
 - color octet (“NLO COM”): Li, Song, Zhang, Ma, Phys. Rev. D83 (2011) 014001
 - color singlet (“LO CSM”): Lansberg, Lorce, arXiv:1303.5327
- Apparent large disagreement between theory and DPS-subtracted rate
- Suggestions from theory community of large feeddown from χ_c states

Conclusion

- $W+J/\psi$ provides a potentially very interesting window into strong force dynamics, in both quarkonium production and proton structure.
- ATLAS has made a 5.3σ observation of this process with 4.6 fb^{-1} of 7 TeV data. [ATLAS-CONF-2013-042](#)
- Low statistics make it hard to disentangle different components but distributions are suggestive of both SPS and DPS processes.
- Result appears to significantly exceed early theoretical expectations for SPS processes.
